Linear Search and Binary Search are techniques for finding elements in a collection.

Linear Search checks each element sequentially until the target is found or the list ends. It works on both sorted and unsorted data but has linear time complexity.

Binary Search works only on sorted data. It repeatedly divides the search space in half, resulting in logarithmic time complexity. This makes it much faster for large datasets.

Linear Search is simple and flexible, while Binary Search is efficient but requires sorted input. The choice depends on dataset size and structure.

Linear Search and Binary Search are techniques for finding elements in a collection.
